Method C v2: Bayesian-symmetric monotone ansatz ladder (structural deficit across τ)

Fixed-Point Factory — Method C v2 ladder

June 2026

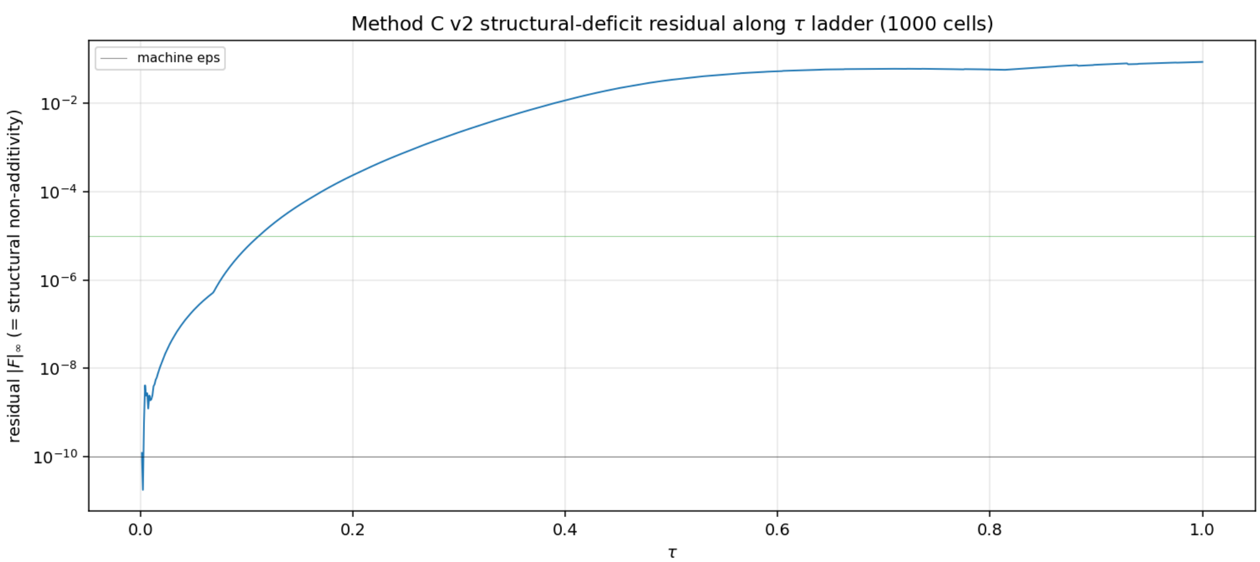
What this measures

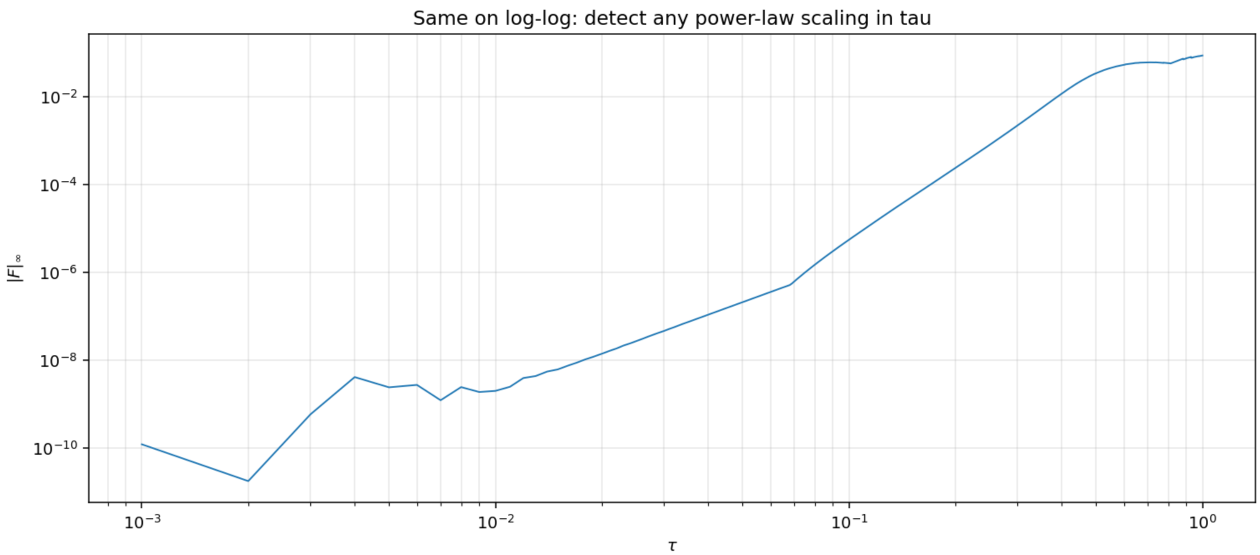
For each τ, fit the parametric family

$$P(u_1, u_2, u_3) = \sigma\big(h(u_1) + h(u_2) + h(u_3)\big)$$

where h is odd and increasing ($h(u) = \int_0^u \sigma_*^2(s)\, ds$ with σ_* an even Cheby polynomial of degree 8). 5 unknowns. The fit residual $|F|_\infty = \max|\Phi[P] - P|$ measures **how much the equilibrium needs cross-signal joint structure beyond the additive form**. This is the structural deficit, separated from kernel-band bias.

Residual along the τ ladder





Same on log-log: detect any power-law scaling in tau
